

## Section I.4. Cosets and Counting

**Note.** In this section, we generalize the idea of congruence modulo  $m$  on  $\mathbb{Z}$  to a more general setting. This is the same approach taken in an undergraduate class, but we will deal in a more hands-on way with the equivalence relation here.

**Definition I.4.1.** Let  $H$  be a subgroup of group  $G$  and  $a, b \in G$ .  $a$  is *right congruent* to  $b$  modulo  $H$ , denoted  $a \equiv_r b \pmod{H}$  if  $ab^{-1} \in H$ .  $a$  is *left congruent* to  $b$  modulo  $H$ , denoted  $a \equiv_\ell b \pmod{H}$ , if  $a^{-1}b \in H$ .

**Note.** We use left and right congruent to define left and right cosets. As in undergraduate algebra, we'll use the cosets to prove Lagrange's Theorem and, under "appropriate conditions" make a group out of the cosets.

**Theorem I.4.2.** Let  $H$  be a subgroup of a group  $G$ .

- (i) Right and left congruence modulo  $H$  are each equivalence relations on  $G$ .
- (ii) The equivalence class of  $a \in G$  under right (and left) congruence modulo  $H$  is the set  $Ha = \{ha \mid h \in H\}$  (and  $aH = \{ah \mid h \in H\}$  for left congruence).
- (iii)  $|Ha| = |H| = |aH|$  for all  $a \in G$ .

The set  $Ha$  is a *right coset* of  $H$  in  $G$  and  $aH$  is a *left coset* of  $H$  in  $G$ .

**Note.** We see from the proof that  $|Ha| = |aH| = |H|$ , even if  $H$  is infinite since the existence of a bijection is established.

**Corollary I.4.3.** Let  $H$  be a subgroup of group  $G$ .

- (i)  $G$  is the union of the right (and left) cosets of  $H$  in  $G$ .
- (ii) Two right (or two left) cosets of  $H$  in  $G$  are either disjoint or equal.
- (iii) For  $a, b \in G$ , we have that  $Ha = Hb$  if and only if  $ab^{-1} \in H$ , and  $aH = bH$  if and only if  $a^{-1}b \in H$ .
- (iv) If  $\mathcal{R}$  is the set of distinct right cosets of  $H$  in  $G$  and  $\mathcal{L}$  is the set of distinct left cosets of  $H$  in  $G$ , then  $|\mathcal{R}| = |\mathcal{L}|$ .

**Note.** Parts (i) and (ii) imply that the right (and left) cosets of  $H$  in  $G$  partition  $G$ .

**Note.** In additive notation, we have  $a \cong_r b \pmod{H}$  if and only if  $a - b \in H$ . The equivalence class of  $a \in G$  is the right coset  $H + a = \{h + a \mid h \in H\}$ .

**Definition I.4.4.** Let  $H$  be a subgroup of a group  $G$ . The *index* of  $H$  in  $G$ , denoted  $[G : H]$ , is the cardinal number of the set of distinct right (or left) cosets of  $H$  in  $G$ .

**Note.**  $G$  and  $H$  may be infinite while  $[G : H]$  is finite:  $[\mathbb{Z} : \langle m \rangle] = m$ . The extreme values of the index occur when  $H = \{e\}$  and  $H = G$ :  $[G : \{e\}] = |G|$  and  $[G : G] = 1$ .

**Theorem I.4.5.** If  $K, H, G$  are groups with  $K < H < G$ , then  $[G : K] = [G : H][H : K]$ . If any two of these indices are finite, then so is the third.

**Note.** The proof of the well-known Lagrange's Theorem is now easy.

**Corollary I.4.6. Lagrange's Theorem.**

If  $H$  is a subgroup of a group  $G$ , then  $|G| = [G : H]|H|$ . In particular, if  $G$  is finite then the order  $|a|$  of  $a \in G$  divides  $|G|$ ;  $|H|$  divides  $|G|$ .

**Note.** The converse of the “in particular” comment in Lagrange's Theorem does not hold. For example, the alternating group  $A_4$  of order 12 (defined in Section I.6) does not have a subgroup of order 6; this is to be shown in Exercise I.6.8. So it is natural to ask: “For a given divisor  $d$  of the order of a finite group  $G$ , under what conditions does  $G$  have a subgroup of order  $d$ ?” This is partially addressed in [Section II.5. The Sylow Theorems](#); see Cauchy's Theorem (Theorem II.5.2) and the First Sylow Theorem (Theorem II.5.7).

**Note.** For group  $G$  and  $H, K$  subsets of  $G$ , we denote the set  $\{hk \mid h \in H, k \in K\}$  as  $HK$ . If  $H$  and  $K$  are subgroups of  $G$ , then  $HK$  may or may not (see Exercise I.4.7) be a subgroup of  $G$ . Now for some “counting” results.

**Theorem I.4.7.** Let  $H$  and  $K$  be finite subgroups of a group  $G$ . Then  $|HK| = |H||K|/|H \cap K|$ .

**Proposition I.4.8.** If  $H$  and  $K$  are subgroups of a group  $G$ , then  $[H : H \cap K] \leq [G : K]$ . If  $[G : K]$  is finite, then  $[H : H \cap K] = [G : K]$  if and only if  $G = KH$ .

**Proposition I.4.9.** Let  $H$  and  $K$  be subgroups of finite index of group  $G$ . Then  $[G : H \cap K]$  is finite and  $[G : H \cap K] \leq [G : H][G : K]$ . Furthermore,  $[G : H \cap K] = [G : H][G : K]$  if and only if  $G = HK$ .
