## Chapter 3. Conic Sections

### 3.3. The Hyperbola—Proofs of Theorems

## Theorem 3.3.A (Apollonius' Proposition III.51)

### Theorem 3.3.A. (Apollonius' Proposition III.51)

The intersection of a double cone and a plane that is more steep than the generators of the cone is a locus of all points in a plane whose distances from two fixed points in the plane (called foci) have a constant difference.

**Proof.** Let  $\pi$  be a plane intersecting a double cone and let  $\pi$  be more steep than the generators of the double cone. Let  $P$  be an arbitrary point on the intersection of plane  $\pi$  and the lower cone (a similar argument holds when  $P$  is on the upper cone).

## Theorem 3.3.A (Apollonius' Proposition III.51); Cont. 1

**Proof (continued).** Next, introduce two Dandelin spheres, one in the lower cone tangent to  $\pi$  and one in the upper cone tangent of  $\pi$ , and let  $F$  and  $F'$  be the points of tangency of the upper and lower Dandelin cones with plane  $\pi$ , respectively. Let circle  $C$  be the intersection of the lower cone and  $\pi$  and circle  $C'$  be the intersection of the lower cone and  $\pi$  and circle  $C'$  be the intersection of the upper cone and  $\pi$ . See Figure 3.10 (left).

## Theorem 3.3.A (Apollonius' Proposition III.51); Cont. 2

**Proof (continued).** Now the plane containing circle  $C$  intersects plane  $\pi$  in a line. Let  $B$  be the point on this line that is above point  $P$  (see Figure 3.10, right). Since  $\pi$  is less steep than the generator  $\overleftrightarrow{AP}$  of the cone, then  $PB$  is longer than  $PA$  (compare the slopes of these line segments in the plane containing points  $P$ ,  $A$ , and  $B$ ). Define the factor by which  $PB$  is longer than  $PA$  as  $1/e$  where  $e > 1$ .

Fig. 3.10. A hyperbola as the intersection of a cone with a plane

### Theorem 3.3.A (Apollonius' Proposition III.51); Cont. 3

**Proof (continued).** Since parameter  $1/e$  is determined by the slope of a generator of the cone and the slope of plane  $\pi$  (more appropriately,  $1/e$  is determined by the slopes of the *cross sections* of the cone and  $\pi$  in the plane containing points  $P$ ,  $A$ , and  $B$ ), then  $1/e$  is independent of point  $P$ . Notice that both  $PF$  and  $PA$  are tangent to the Dandelin sphere, so they have the same lengths (as argued at the beginning of the proof of Theorem 3.1).

Fig. 3.10. A hyperbola as the intersection of a cone with a plane

### Theorem 3.3.A (Apollonius' Proposition III.51); Cont. 4

**Proof (continued).** Extend  $AP$  through the vertex of the double cone and then to the second cone and circle  $C'$  at point  $A'$ . Again,  $PF'$  and  $PA'$  are the same length. Next, the plane containing circle  $C'$  intersects plane  $\pi$  in a line. Let  $B'$  be the point on this line that is above  $P$  (s that  $PB$  and  $PB'$  are collinear; point  $B'$  is not in Figure 3.10). Just as  $PB$  is shorter than  $PA$  above,  $PB'$  is shorter than  $PA'$  by a factor of  $1/e$  and parameter  $q/e$  is independent of  $P$ .

Fig. 3.10. A hyperbola as the intersection of a cone with a plane

### Theorem 3.3.A (Apollonius' Proposition III.51); Cont. 5

**Proof (continued).** With  $l$  as the length of  $PF$  (and  $PA$ ) then  $PB$  is length  $l/e$ . With  $l'$  as the length of  $PF'$  (and  $PA'$ ) then  $PB'$  is length  $l'/e$ . For any point  $P$  on the lower branch of the hyperbola, we have that the length of  $PF'$  minus the length of  $PF$  is  $l' - l$ . Also, for any point on the lower branch,  $l'/e - l/e$  is the same (since  $PB$  and  $PB'$  are collinear). Therefore,  $l' - l$  is the same for all points  $P$  on the lower branch of the hyperbola. That is the distances of  $P$  from two fixed points in the plane have a constant difference, as claimed.  $\square$
